That's great and all, but I'm so tired of being limited by this stupid licensing, I want to build a fast & easily multithreaded packet sniffer from scratch. The original reason we started on a single thread packet sniffer was because a single thread would be enough to sniff all packets. On Linux, I've been experimenting with packet filtering on specific network devices using ipchains. The result is a lot of knowledge but also a headache because I've been using ipchains for way too long to remember everything by heart. If we compare how regular packet filtering is done from a packet sniffer, here's a list of the main pros and cons. Advantages. Main advantage of packet filtering on a single device is that it's possible to filter packets on a certain protocol. Even if the sniffer is multithreaded, it's very hard to listen to more than one connection at the same time. Disadvantages. Limitations on the protocol for which you want to filter packets (. Analyse a single protocol in great details) or if you're only interested in the length of specific packets or too. To go the opposite way, packet filtering requires you to filter packets based on a detailed protocol analysis. Another advantage of using ipchains. Only ipchains supports packet filtering and is able to do this with specific protocols at the same time. Reading ipchains To understand how ipchains works, we'll analyse what we did to our ipchains rules file. ipchains --help Looking at the ipchains man page. we see several options. ipchains --help Print all the available options ipchains --help Print all the available options ipchains --help Print all the available options ipchains --help Print all the available options ipchains --help Print all the available options ipchains Print all the available options ipchains Print all the available options ipchains Print all the available options ipchains --help Print all the available options Print all the available options ipchains --help Print all the available options Print all the available options ipchains --help Print all the available options Print all the available options Print all
